

Experimental and Causal-Comparative Designs

Chapter 10

What do we need to have a good design? Good sampling, changing one variable and keeping everything else the same

Design refers to the total architectural plan and the underlying structure of the research framework.

Experimental design refers to the entire experimental approach to a research problem.

The difference between research and an experiment is:

1. Research requires planning
2. Research determines facts
3. Experiments require planning
4. Experiments determine facts

A control group:

1. Undergoes all treatments
2. Undergoes no treatments
3. Undergoes a special treatment
4. Undergoes every other treatment

2

An independent variable:

1. Is established by the researcher
2. Is established by the dependent variable
3. Is plotted on the y axis
4. Cannot be plotted

1

A factorial design:

1. Compares multiple treatments at once
2. Compares multiple treatments separately
3. Compares multiple treatments at once and separately
4. Compares only one treatment

Descriptive statistics:

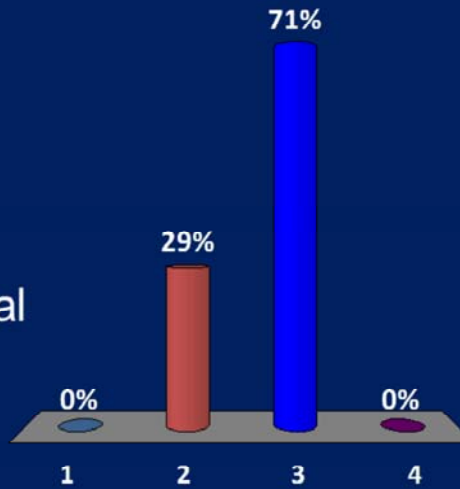

1. Explains what the data look like
2. Uses statistics to find significant differences
3. Measures the difference between right and wrong data
4. Identifies bad data

1

Parametric statistics:

1. Require a normal distribution
2. Require interval or ratio data
3. Require interval or ratio data and a normal distribution
4. Do not have requirements

3

With Type II error:

1. We cannot make any conclusions
2. We conclude that a chance occurrence was not due to chance
3. We conclude that a result is due to chance when it is not

Nominal data:

1. Reflects a particular order or sequence
2. Reflects categories
3. Reflects standard, equal units of measurement with an arbitrary 0 point
4. Reflects standard, equal units of measurement with a specific 0 point

2

Experiment vs. Research

Experiment: determining a fact...measuring N content of soil (for a farmer)

Research: determining a fact but also includes interpreting findings...measuring N content of soil under different types of vegetation, different landscape position, etc.....must be planned
Also research needs to be planned

Control

- Keep things constant
- Include a control group
- Randomly assign people to groups
- Use matched pairs
- Expose to all treatments and control
- Statistics

1 Part of internal validity

2 Control for confounding variables: whenever samples are different in ways in addition to the treatments we have applied (greenhouse example)

Control group: Including a control group is important to rule out confounding variables (i.e. placebo effect) but the control group has to be treated the same as the other groups. (see next slide)

Random: so that differences between people is averaged among the whole treatment group

Matched pairs: used when groups are already present (students in particular instructional programs)...select two individuals from each group that have the same characteristics

Expose: Allow each individual to undergo all treatments and assess the effects of each treatment independently (also called a within-subjects or repeated measures design) (partitioning lecture example)

Statistics: certain statistical approaches can be used to control for confounding variables but using research designs are the best way

Control

It is very important to do the same thing to the control group as is done to the variable groups, everything except for the variable itself.

In applying biosolids a large truck was used for spreading. The truck was driven over the control plot without spreading manure to make everything the same.

Variables

- Independent
- Dependent

Independent: variables that the researcher manipulates

Dependent: variables that are influenced by the independent variable

Example: blood pressure medications

When you graph data, the independent variable is found on the x axis and the dependent variable is on the y-axis

Experimental Designs

- Pre-experimental

One-shot experimental case study

Group	Time →	
Group 1	Tx	Obs

Quick tests that are usually used to identify if an idea will work

Subjects are not randomly assigned

Experimental Designs

Pre-experimental designs (con't)

One-group pretest-posttest design

Group	Time →		
Group 1	Obs	Tx	Obs

Static group comparison

Group	Time →	
Group 1	Tx	Obs
Group 2	-----	Obs

Experimental Designs

- True experimental designs

Pretest-posttest control group design

Group	Time →		
Group 1	Obs	Tx	Obs
Group 2	Obs	-----	Obs

Greater degree of control
and greater internal validity

Random assignment to
groups

To study the effect of an influence on a carefully controlled sample

Can identify if any changes take place due to the treatment and if so then we can rule out other possible explanations because we have a control group that was randomly assigned.

i.e. soil concentration of N before growing legumes, soil concentration after growing legumes

Experimental Designs

True experimental designs (con't)

Solomon Four-Group Design

Group	Time →		
Group 1	Obs	Tx	Obs
Group 2	Obs	-----	Obs
Group 3	-----	Tx	Obs
Group 4	-----	-----	Obs

To investigate the possible effect of pretesting...if group 3 and 4 give the same results as group 1 and 2, respectively, then there is no effect of pretesting.

Enhances the external validity of the study

Experimental Designs

True experimental designs (con't)

Posttest-only control group design

Group	Time →	
Group 1	Tx	Obs
Group 2	-----	Obs

To evaluate a situation that cannot or should not be pretested
Similar to static group comparison but is randomly sampled.
i.e. Plant height after applying manure

Experimental Designs

- Quasi-experimental designs

Nonrandomized control group pretest-posttest design

Group	Time →		
Group 1	Obs	Tx	Obs
Group 2	Obs	-----	Obs

Used in situations where random selection and assignment are not possible

Must be aware of the specific variables that the design fails to control and take them into account when interpreting the data

Comparing pretest results can indicate degree of similarity between groups with respect to the dependent variable

Experimental Designs

Quasi-experimental designs (con't)

Time-series experiment

Group	Time →				
Group 1	Obs	Obs	Tx	Obs	Obs

Control group, time-series design

Group	Time →				
Group 1	Obs	Obs	Tx	Obs	Obs
Group 2	Obs	Obs	-----	Obs	Obs

Time-series: external validity is increased by repeating the experiment in different places under different conditions...some other unrecognized event may occur at the same time that the treatment occurs

Control group: has greater internal validity than the previous

Experimental Designs

Quasi-experimental designs (con't)

Equivalent time-samples design

Group	Time →					
Group 1	Tx	Obs	-----	Obs	Tx	Obs

Uses a repeated measures approach to control for the effects of outside events better than the previous two designs

Experimental variable is sometimes present sometimes not and observations are made at regular intervals

i.e. effect of audiovisual aids on student's learning

Can also alternate with different treatments

Causal-Comparative Designs

- Used when it is impossible or unethical to manipulate certain variables
- Also known as Ex post facto

HOUSE

Cannot introduce a virus, withhold instruction, ask parents to abuse their children, or modify a person's personality

i.e. a disease is discovered and researchers look back at previous cases to find evidence of causes (genetic, environmental...House)

The researcher looks at conditions that have already occurred and then collects data to investigate a possible relationship between these characteristics and subsequent characteristics or behaviors

Factorial Designs

- Two or more independent variables are studied
- Involves random assignment

Group	Time →		
Group 1	T1	T2	Obs
Group 2	T1	-----	Obs
Group 3	-----	T2	Obs
Group 4	-----	-----	Obs

You can compare the effect of T1 by itself, the effect of T2 by itself and the effect of both (interaction)

Statistics for Quantitative Data

Chapter 11

Explore the Data

Before applying statistical calculations, explore the data by creating a visual representation.

Where two variables are concerned, one of the variables may become more dominant and govern the meaning that emerges in the data.

Look at the list of data...what trends do you observe? (Girls have higher grades than boys). Grades increase with alpha order.

Code, organize, search for data in spreadsheets.

Look for correlations or associations between two variables (i.e. Compare data of different nutrient concentrations with each other, compare across time, temperature, rainfall)

Statistics

- Descriptive
- Inferential

Descriptive: explains what the data look like (mean, standard deviation)
Inferential: helps us make reasonable guesses about a population that is unknown based on a small sample of the population that is known

Statistics allows us to comprehend multitudes of different data as an organized whole

Figure represents plant-growing abilities of students in different disciplines.

Descriptive: summarizes the general nature of the data obtained (average, standard deviation, etc.)

Inferential: identifies the significance of the data ($p < 0.05$)

Scales of Measurement

-Nominal

-Ordinal

-Interval

-Ratio

Nominal: categorical data; can be analyzed statistically by mode (frequency of occurrence), percent, chi-square test

Ordinal: ranking data based on order; can be analyzed statistically by mode, percent, median (halfway point in set of data), percentile rank

Interval: has equal units of measurement and its zero point has been established arbitrarily...can be analyzed statistically using measures that employ addition and subtraction (means, standard deviation)

Ratio: has equal measurement units, and an absolute zero point...can express values in terms of fractions or multiples

Accuracy and Precision

#1 = Accurate and Precise

#2 = Accurate and Not Precise

#3 = Not Accurate and Not Precise

#4 = Precise and Not Accurate

Accuracy (Validity): the ability of an instrument to measure what it is supposed to measure

Precision (Reliability): the consistency with which an instrument gives the same result for the same thing being measured

Parameter and Statistic

Parameters of the population

(What we really want)

μ - mean

σ - standard deviation

p - proportion

Statistics of the sample

(What we actually get)

\bar{x} - sample mean

s - sample standard deviation

\hat{p} - sample proportion

Parameters represent a quality or characteristic of a population. The same characteristic studied on the small sample of the population is called the statistic.

Consider the Data

- Single-group vs. multi-group
- Continuous vs. discrete variables
- Nominal, ordinal, interval, and ratio data
- Normal distribution

Different types of data require different statistical measures.

Continuous variable: reflects an infinite number of possible values falling along a particular continuum (i.e. age)

Discrete variable: has a small and finite number of possible values (i.e. grades in school)

Nominal data: numbers are used to identify different categories (i.e. 1 = male, 2 = female)

Ordinal data: the values reflect a particular order or sequence (i.e. class rank) but do not give information on how much they differ from one another

Interval data: data that reflects standard and equal units of measurement...reflect differences in degree like ordinal data but also how much difference exists. Zero does not necessarily mean a total absence (i.e. IQ scores)

Ratio data: similar to interval data, but zero does have an actual value

Perceptions of social media use for Teaching and Extension

<25	25-34	35-44	45-54	55-64	65+
I use social media to its fullest extent for my programming.					
1.92	2.11	2.00	2.09	1.73	1.65

SA = 4. A = 3. D = 2. SD = 1

This is a continuation of the questions that were asked in the previous slide. So we've got that its useful and important and can be applied to teaching and extension....so are we using it to its fullest extent? No, everyone disagrees with that. There may be a couple of reasons for this...we may not want to use it to its fullest extent (could be time consuming, could be features that don't apply)...also we might not know how to use it to the fullest extent. So that leads us into the next question and kind of the main focus of the symposium....using social media more effectively. Everyone agreed that they were interested in using it more effectively...so that means everyone that filled out this survey should be right here in this room!

Consider the Data

- Single-group vs. multi-group
- Continuous vs. discrete variables
- Nominal, ordinal, interval, and ratio data
- Normal distribution

Different types of data require different statistical measures.

Continuous variable: reflects an infinite number of possible values falling along a particular continuum (i.e. age)

Discrete variable: has a small and finite number of possible values (i.e. grades in school)

Nominal data: numbers are used to identify different categories (i.e. 1 = male, 2 = female)

Ordinal data: the values reflect a particular order or sequence (i.e. class rank) but do not give information on how much they differ from one another

Interval data: data that reflects standard and equal units of measurement...reflect differences in degree like ordinal data but also how much difference exists. Zero does not necessarily mean a total absence (i.e. IQ scores)

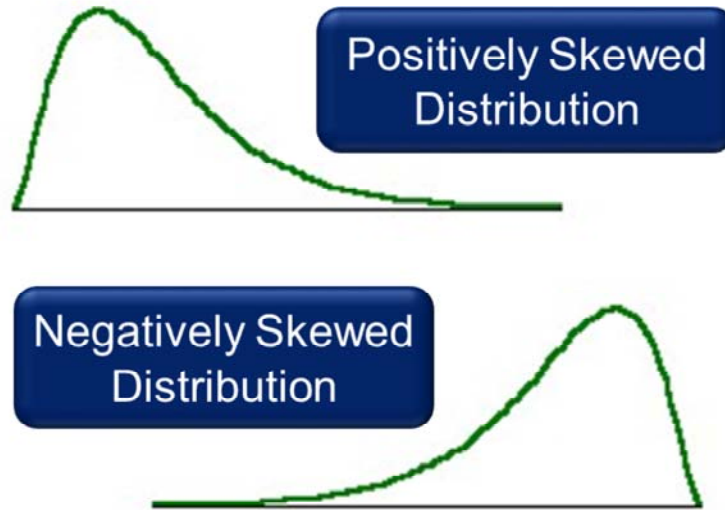

Ratio data: similar to interval data, but zero does have an actual value

Normal Distribution

Normal distribution: Many characteristics of human population and the natural world reflect this pattern; some extremes but most average
It has horizontal symmetry, its highest point is at its midpoint, and predictable percentages lie within any given portion of the curve.

Skewed Distributions

Can be positively or negatively skewed, or exceptionally pointy or flat

Parametric and Nonparametric

Parametric: The data reflect an interval or ratio scale, the data fall in a normal distribution

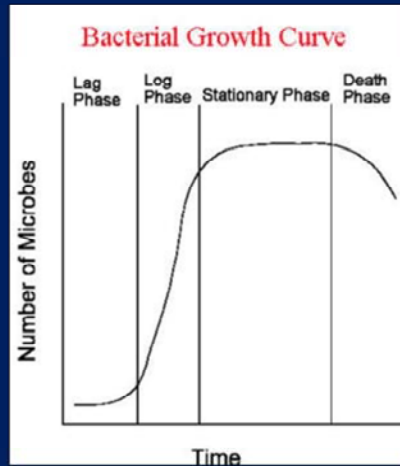

Nonparametric: does not include the above assumptions

Parametric statistics are the most powerful statistical procedures while nonparametric procedures are appropriate for relatively simple analyses. Some statistical analyses produce valid results for data that are normal or nonnormal, it depends upon the assumptions for each test.

Speak with professors that are involved in the same type of research that you are involved in to get an idea of some of the statistical tests that might be appropriate in your work.

Descriptive Statistics

- Measures of central tendency

Measures of central tendency: mean, median, mode

Arithmetic mean: used for data of interval or ratio scales and in a normal distribution

Geometric mean: used for data of ratio scales that fall in an ogive curve (growth data...reaches a plateau point)...measured by multiplying by N values, finding the Nth root

Why are we interested in means? Because they are the best predictor of the population

Descriptive Statistics

- Measures of central tendency
- Measures of variation

$$SD = \sqrt{\frac{\sum (x - \bar{x})^2}{n}}$$

The more spread that exists, the less valid the average becomes.

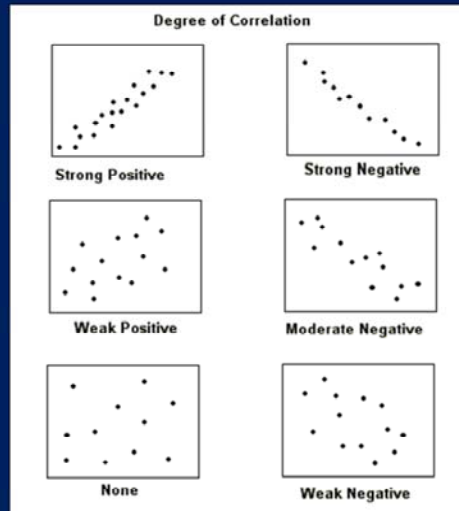

Range of the data...interquartile range involved percentiles with the median as the 50th percentile, the interquartile range is the range that exists between the 25th and 75th quartiles. Can be used with ordinal, interval, and ratio data, good for skewed data.

Also can use standard deviation which employs the mean. Can be used with interval and ratio data, good for normal distribution.

Variance is the square of the SD and can be used for interval and ratio scales that are normally distributed.

Descriptive Statistics

- Measures of central tendency
- Measures of variation
- Correlation

What is correlation? What is a correlation coefficient? What is the range? What types of values would you expect for the above graphs? What does it mean? (i.e. causal vs. association).

Different coefficients exist but the most common is the Pearson's, it is used for continuous data from a normal distribution. The book has a table of some of the different types involved.

Inferential Statistics

$$\sigma = \frac{\sigma}{\sqrt{n}}$$

Standard error of the
population mean

$$\sigma = \frac{s}{\sqrt{n - 1}}$$

Estimated
standard error of
the population
mean

- Point estimate
- Interval estimate

Estimates from inferential statistics assume random sampling that is representative of the population

Different samples selected from the same population will have slightly different estimates of the population, therefore we need to estimate this error...the error would be that depicted in the first figure but we do not know the standard deviation of the population so we use the standard deviation of the sample.

Point estimate: a single statistic that is taken as the best indication of the corresponding population parameter (i.e. sample mean)

Interval estimate: a specified range between which we estimate that practically all the values will lie (i.e. confidence interval...95%, 99%)

Inferential Statistics

- Statistical hypothesis testing
- Testing errors

HYPOTHESIS TESTING OUTCOMES		Reality	
		The Null Hypothesis is True	Null Hypothesis is false
R e s e a r c h	The Null Hypothesis is True	Accurate $1 - \alpha$ 	Type II Error β 
	Null Hypothesis is false	Type I Error α 	Accurate $1 - \beta$ 

Test the null hypothesis...the null hypothesis postulates that any result observed is the result of chance alone.

Involves comparing the distribution of data collected by a researcher with an ideal, or hypothetical distribution.

If something occurs that has a 5% chance of occurring it is considered significant if this level of significance (0.05) is being used...common levels of significance are 0.10, 0.05, 0.01

This is then considered statistically significant and we reject the null hypothesis. When the null hypothesis is rejected, an alternative hypothesis (which may be the research hypothesis) may be supported.

Type I error: occurs when we conclude that a chance occurrence was not due to chance, when in fact it was due to chance. (We incorrectly reject the null hypothesis).

Type II error: we conclude that a result is due to chance when it is not (We fail to reject a null hypothesis that is false).

To reduce the chance of having Type I errors you can reduce your level of significance but this increases the chance of making Type II errors.

To reduce the chance of making Type II errors you can increase the level of significance, use a large sample size, increase the validity and reliability of your tests, and use parametric statistical analyses rather than nonparametric ones where possible.

We can also increase our chances of making Type I errors the more statistical analyses we perform.

The difference between research and an experiment is:

1. Research requires planning
2. Research determines facts
3. Experiments require planning
4. Experiments determine facts

A control group:

1. Undergoes all treatments
2. Undergoes no treatments
3. Undergoes a special treatment
4. Undergoes every other treatment

2

An independent variable:

1. Is established by the researcher
2. Is established by the dependent variable
3. Is plotted on the y axis
4. Cannot be plotted

1

A factorial design:

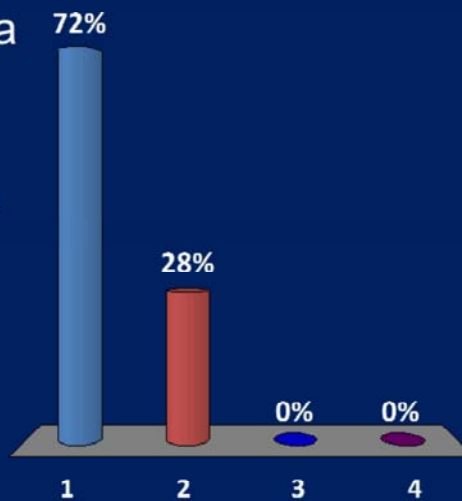

1. Compares multiple treatments at once
2. Compares multiple treatments separately
3. Compares multiple treatments at once and separately
4. Compares only one treatment

3

Descriptive statistics:

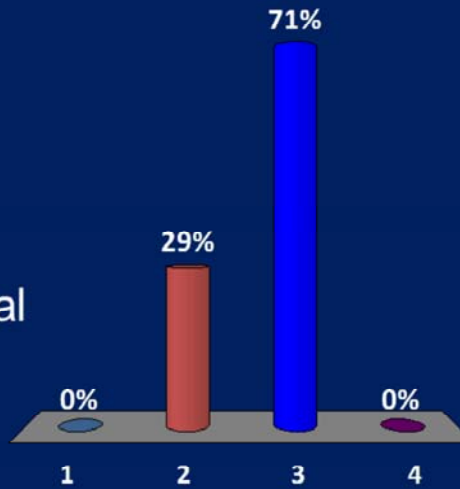

1. Explains what the data look like
2. Uses statistics to find significant differences
3. Measures the difference between right and wrong data
4. Identifies bad data

1

Parametric statistics:

1. Require a normal distribution
2. Require interval or ratio data
3. Require interval or ratio data and a normal distribution
4. Do not have requirements

With Type II error:

1. We cannot make any conclusions
2. We conclude that a chance occurrence was not due to chance
3. We conclude that a result is due to chance when it is not
